Isospectral Property of Hamiltonian Boundary Value Methods (HBVMs) and their blended implementation

L. Brugnano · **F. Iavernaro** · **D. Trigiante**

February 6, 2010.

Abstract One main issue, when numerically integrating autonomous Hamiltonian systems, is the long-term conservation of some of its invariants, among which the Hamiltonian function itself. Recently, a new class of methods, named *Hamiltonian Boundary Value Methods (HBVMs)* has been introduced and analysed [5], which are able to exactly preserve polynomial Hamiltonians of arbitrarily high degree. We here study a further property of such methods, namely that of having, when cast as Runge-Kutta methods, a matrix of the Butcher tableau with the same spectrum (apart the zero eigenvalues) as that of the corresponding Gauss-Legendre method, independently of the considered abscissae. Consequently, HBVMs are always perfectly *A*-stable methods. Moreover, this allows their efficient *blended* implementation, for solving the generated discrete problems.

1 Introduction

Hamiltonian problems are of great interest in many fields of application, ranging from the macro-scale of celestial mechanics, to the micro-scale of molecular dynamics. They have been deeply studied, from the point of view of the mathematical analysis, since two centuries. Their numerical solution is a more recent field of investigation, which has led to define symplectic methods, i.e., the simplecticity of the discrete map, considering that, for the continuous flow, simplecticity implies the conservation of $H(y)$. However, the conservation of the Hamiltonian and simplecticity of the flow cannot be satisfied at the same time unless the integrator produces the exact solution (see [16, page 379]). More recently, the conservation of energy has been approached by means of the definition of the *discrete line integral*, in a series of papers [18,19,20, 21,22], leading to the definition of *Hamiltonian Boundary Value Methods (HBVMs)* [3,4,5,6], which are a class of methods able to preserve, for the discrete solution, polynomial Hamiltonians of arbitrarily high degree (and then, a *practical* conservation of any sufficiently differentiable Hamiltonian). In more details, in [5], HBVMs based on Lobatto nodes have been analysed, whereas in [6] HBVMs based on Gauss-Legendre abscissae have been considered. In the last reference, it has been actually shown that both formulae are essentially equivalent to each other, in the sense that they share the same order (twice the number of *fundamental stages*) and stability properties, and both methods provide the very same numerical solution, when the number of the so called *silent stages* tends to infitiny.[1] In this paper this conclusion if further supported, since we prove that all such methods, when cast as Runge-Kutta methods, have the corresponding matrix of the tableau, whose nonzero eigenvalues coincide with those of the corresponding Gauss-Legendre formula (isospectral property of HBVMs).

This property can be used to define an efficient iteration for solving the discrete problems generated by the methods, via their *blended implementation*. Indeed, after posing HBVMs in block BVM form, they can be recast in the framework of *blended implicit methods*, which have been studied in a series of papers [2,7,8,9,10,11,12, 13,15] (see also C. Magherini's PhD Thesis [23]). The latter methods have been successfully implemented in the two computational codes `BiM` and `BiMD` [24]; the latter code is also included in the current release of the "Test Set for IVP Solvers" [25].

With this premise, the structure of the paper is the following: in Section 2 the basic facts about HBVMs are recalled; in Section 3 we state the main result of this paper, concerning the isospectral property; in Section 4 the discrete problem to be actually solved is defined; in Section 5 it is shown that a corresponding *blended iteration* can be devised for its efficient solution, which can be tuned by choosing a free parameter; in Section 6 the optimal choice of the free parameter is done, on the basis of the isospectral property of HBVM(k,s), by using a linear analysis of convergence; finally, in Section 7 a few concluding remarks are given.

[1] Actually, they both provide the same numerical solution also when the Hamiltonian is a polynomial and the number of *silent stages* is high enough to ensure the conservation property of the Hamiltonian function itself (see (2.8)).

2 Hamiltonian Boundary Value Methods

The arguments in this section are worked out starting from the arguments used in [5, 6] to introduce and analyse HBVMs. We consider canonical Hamiltonian problems in the form

$$\dot{y} = J\nabla H(y), \qquad y(t_0) = y_0 \in \mathbb{R}^{2m}, \tag{2.1}$$

where J is a skew-symmetric constant matrix, and the Hamiltonian $H(y)$ is assumed to be sufficiently differentiable. The key formula which HBVMs rely on, is the *line integral* and the related property of conservative vector fields:

$$H(y_1) - H(y_0) = h\int_0^1 \dot{\sigma}(t_0+\tau h)^T \nabla H(\sigma(t_0+\tau h))\mathrm{d}\tau, \tag{2.2}$$

for any $y_1 \in \mathbb{R}^{2m}$, where σ is any smooth function such that

$$\sigma(t_0) = y_0, \qquad \sigma(t_0+h) = y_1. \tag{2.3}$$

Here we consider the case where $\sigma(t)$ is a polynomial of degree s, yielding an approximation to the true solution $y(t)$ in the time interval $[t_0, t_0+h]$. The numerical approximation for the subsequent time-step, y_1, is then defined by (2.3).

After introducing a set of s distinct abscissae

$$0 < c_1, \ldots, c_s \le 1, \tag{2.4}$$

we set

$$Y_i = \sigma(t_0 + c_i h), \qquad i = 1, \ldots, s, \tag{2.5}$$

so that $\sigma(t)$ may be thought of as an interpolation polynomial, interpolating the *fundamental stages* Y_i, $i = 1, \ldots, s$, at the abscissae (2.4). We observe that, due to (2.3), $\sigma(t)$ also interpolates the initial condition y_0.

Remark 1 *Sometimes, the interpolation at t_0 is explicitly required. In such a case, the extra abscissa $c_0 = 0$ is formally added to (2.4). This is the case, for example, of a Lobatto distribution of the abscissae [5].*

Let us consider the following expansions of $\dot{\sigma}(t)$ and $\sigma(t)$ for $t \in [t_0, t_0+h]$:

$$\dot{\sigma}(t_0+\tau h) = \sum_{j=1}^{s} \gamma_j P_j(\tau), \qquad \sigma(t_0+\tau h) = y_0 + h\sum_{j=1}^{s} \gamma_j \int_0^\tau P_j(x)\,\mathrm{d}x, \tag{2.6}$$

where $\{P_j(t)\}$ is a suitable basis of the vector space of polynomials of degree at most $s-1$ and the (vector) coefficients $\{\gamma_j\}$ are to be determined. We shall consider an *orthonormal basis* of polynomials on the interval $[0,1]$, i.e.:

$$\int_0^1 P_i(t)P_j(t)\mathrm{d}t = \delta_{ij}, \qquad i, j = 1, \ldots, s, \tag{2.7}$$

where δ_{ij} is the Kronecker symbol, and $P_i(t)$ has degree $i-1$. Such a basis can be readily obtained as

$$P_i(t) = \sqrt{2i-1}\,\hat{P}_{i-1}(t), \qquad i = 1, \ldots, s,$$

with $\hat{P}_{i-1}(t)$ the shifted Legendre polynomial, of degree $i-1$, on the interval $[0,1]$.

Remark 2 *From the properties of shifted Legendre polynomials (see, e.g., [1] or the Appendix in [5]), one readily obtains that the polynomials* $\{P_j(t)\}$ *satisfy the three-terms recurrence relation:*

$$P_1(t) \equiv 1, \qquad P_2(t) = \sqrt{3}(2t-1),$$
$$P_{j+2}(t) = (2t-1)\frac{2j+1}{j+1}\sqrt{\frac{2j+3}{2j+1}}P_{j+1}(t) - \frac{j}{j+1}\sqrt{\frac{2j+3}{2j-1}}P_j(t), \quad j \geq 1.$$

We shall also assume that $H(y)$ is a polynomial, which implies that the integrand in (2.2) is also a polynomial so that the line integral can be exactly computed by means of a suitable quadrature formula. It is easy to observe that in general, due to the high degree of the integrand function, such quadrature formula cannot be solely based upon the available abscissae $\{c_i\}$: one needs to introduce an additional set of abscissae $\{\hat{c}_1, \ldots, \hat{c}_r\}$, distinct from the nodes $\{c_i\}$, in order to make the quadrature formula exact:

$$\int_0^1 \dot{\sigma}(t_0+\tau h)^T \nabla H(\sigma(t_0+\tau h))\mathrm{d}\tau = \tag{2.8}$$
$$\sum_{i=1}^{s} \beta_i \dot{\sigma}(t_0+c_i h)^T \nabla H(\sigma(t_0+c_i h)) + \sum_{i=1}^{r} \hat{\beta}_i \dot{\sigma}(t_0+\hat{c}_i h)^T \nabla H(\sigma(t_0+\hat{c}_i h)),$$

where β_i, $i = 1, \ldots, s$, and $\hat{\beta}_i$, $i = 1, \ldots, r$, denote the weights of the quadrature formula corresponding to the abscissae $\{c_i\} \cup \{\hat{c}_i\}$, i.e.,

$$\beta_i = \int_0^1 \left(\prod_{j=1, j\neq i}^{s} \frac{t-c_j}{c_i-c_j} \right) \left(\prod_{j=1}^{r} \frac{t-\hat{c}_j}{c_i-\hat{c}_j} \right) \mathrm{d}t, \qquad i = 1, \ldots, s,$$
$$\hat{\beta}_i = \int_0^1 \left(\prod_{j=1}^{s} \frac{t-c_j}{\hat{c}_i-c_j} \right) \left(\prod_{j=1, j\neq i}^{r} \frac{t-\hat{c}_j}{\hat{c}_i-\hat{c}_j} \right) \mathrm{d}t, \qquad i = 1, \ldots, r. \tag{2.9}$$

Remark 3 *In the case considered in the previous Remark 1, i.e. when* $c_0 = 0$ *is formally added to the abscissae (2.4), the first product in each formula in (2.9) ranges from* $j = 0$ *to s. Moreover, also the range of* $\{\beta_i\}$ *becomes* $i = 0, 1, \ldots, s$. *However, for sake of simplicity, we shall not consider this case further.*

According to [21], the right-hand side of (2.8) is called *discrete line integral*, while the vectors

$$\hat{Y}_i \equiv \sigma(t_0+\hat{c}_i h), \qquad i = 1, \ldots, r, \tag{2.10}$$

are called *silent stages*: they just serve to increase, as much as one likes, the degree of precision of the quadrature formula, but they are not to be regarded as unknowns since, from (2.6) and (2.10), they can be expressed in terms of linear combinations of the fundamental stages (2.5).

Definition 1 *The method defined by substituting the quantities in* (2.6) *into the right-hand side of* (2.8)*, and by choosing the unknown coefficients* $\{\gamma_j\}$ *in order that the resulting expression vanishes, is called* Hamiltonian Boundary Value Method with *k* steps and degree *s*, *in short* HBVM(*k*,*s*), *where* $k = s + r$ *[5].*

In the sequel, we shall see that HBVMs may be expressed through different, though equivalent, formulations: some of them can be directly implemented in a computer program, the others being of more theoretical interest.

Because of the equality (2.8), we can apply the procedure directly to the original line integral appearing in the left-hand side. With this premise, by considering the first expansion in (2.6), the conservation property reads

$$\sum_{j=1}^{s} \gamma_j^T \int_0^1 P_j(\tau) \nabla H(\sigma(t_0+\tau h)) \mathrm{d}\tau = 0,$$

which, as is easily checked, is certainly satisfied if we impose the following set of orthogonality conditions:

$$\gamma_j = \int_0^1 P_j(\tau) J \nabla H(\sigma(t_0+\tau h)) \mathrm{d}\tau, \qquad j = 1,\dots,s. \tag{2.11}$$

Then, from the second relation of (2.6) we obtain, by introducing the operator

$$\begin{aligned} &L(f;h)\sigma(t_0+ch) = \\ &\sigma(t_0) + h\sum_{j=1}^{s} \int_0^c P_j(x)\mathrm{d}x \int_0^1 P_j(\tau) f(\sigma(t_0+\tau h))\mathrm{d}\tau, \qquad c \in [0,1], \end{aligned} \tag{2.12}$$

that σ is the eigenfunction of $L(J\nabla H;h)$ relative to the eigenvalue $\lambda = 1$:

$$\sigma = L(J\nabla H;h)\sigma. \tag{2.13}$$

Definition 2 *Equation (2.13) is the* Master Functional Equation *(MFE) defining σ [6].*

Remark 4 *Some further details are in order to better elucidate the role of the MFE in devising our methods. First of all we observe that, by definition, the MFE intrinsically brings, with its polynomial solutions $\sigma(t_0+ch)$, the conservation property of the Hamiltonian function: indeed* (2.13) *is equivalent to* (2.8) *under the choice* (2.11)*.*

This means that, when searching for its solutions, one should always take care of the precise dimension of the polynomial vector space, say ν, $H(y)$ is intended to belong to: the higher is ν, the higher must be the number of silent stages (and hence the number of steps k) to guarantee that (2.8) *be satisfied. This explains the way the solutions of the MFE depends on k.*

It is also clear that, assuming the same kind of distribution for all the k the nodes (see later), (2.8) *will be satisfied starting from a suitable number of steps $k \equiv k_\nu$ on. This implies that, for all $k \geq k_\nu$, HBVM(k,s) will define the* same *polynomial σ of degree s, such that $H(\sigma(t_0+h)) = H(\sigma(t_0))$.*

To practically compute σ, we set (see (2.5) and (2.6))

$$Y_i = \sigma(t_0+c_ih) = y_0 + h\sum_{j=1}^{s} a_{ij}\gamma_j, \qquad i = 1,\dots,s, \tag{2.14}$$

where

$$a_{ij} = \int_0^{c_i} P_j(x)\mathrm{d}x, \qquad i,j = 1,\dots,s.$$

Inserting (2.11) into (2.14) yields the final formulae which define the HBVMs class based upon the orthonormal basis $\{P_j\}$:

$$Y_i = y_0 + h\sum_{j=1}^{s} a_{ij}\int_0^1 P_j(\tau)J\nabla H(\sigma(t_0+\tau h))\,\mathrm{d}\tau, \qquad i = 1,\dots,s. \tag{2.15}$$

We recall once again that we are working under the assumption (2.8), namely that the Hamiltonian is a polynomial and that we are considering a sufficient number of additional abscissae $\hat{c}_i$ such that the line integral and its discrete counterpart do coincide. This implies that we can replace the integrals appearing in (2.15) by sums representing the associated quadrature formulae introduced in (2.8), without introducing any discretization error.

This leads back to express the HBVM(k,s) method in terms of the fundamental stages $\{Y_i\}$ and the silent stages $\{\hat{Y}_i\}$ (see (2.10)). By using the notation

$$f(y) = J\nabla H(y), \tag{2.16}$$

we obtain

$$Y_i = y_0 + h\sum_{j=1}^{s} a_{ij}\left(\sum_{l=1}^{s}\beta_l P_j(c_l)f(Y_l) + \sum_{l=1}^{r}\hat{\beta}_l P_j(\hat{c}_l)f(\widehat{Y}_l)\right), \quad i = 1,\dots,s. \tag{2.17}$$

We again stress that the silent stages $\hat{Y}_l$ may be removed from (2.17) by observing that, for example,

$$\hat{Y}_l = \sum_{i=1}^{s}\ell(t_0+\hat{c}_i h)Y_i, \qquad l = 1,\dots,r,$$

where $\ell(t)$ are the cardinal Lagrange polynomials defined on the nodes $t_0 + c_i h$, $i = 1,\dots,s$.

From the above discussion it is clear that formulae (2.15) also make sense in the non-polynomial case. In fact, supposing to choose the abscissae $\{\hat{c}_i\}$ so that the sums in (2.17) converge to an integral as $r \equiv k - s \to \infty$, the resulting formula is again (2.15).

Definition 3 *Formula (2.15) is named* ∞-HBVM of degree s *or* HBVM(∞,s) *[6].*

This implies that HBVMs may be as well applied in the non-polynomial case since, in finite precision arithmetic, HBVMs are undistinguishable from their limit formulae (2.15), when a sufficient number of silent stages is introduced. The aspect of having a *practical* exact integral, for k large enough, was already stressed in [3,5, 6,18,21].

2.1 Runge-Kutta formulation of HBVMs

On the other hand, we emphasize that, in the non-polynomial case, (2.15) becomes an *operative method* only after that a suitable strategy to approximate the integrals appearing in it is taken into account. In the present case, if one discretizes the *Master Functional Equation* (2.12)–(2.13), HBVM(k,s) are then obtained, essentially by extending the discrete problem (2.17) also to the silent stages (2.10). In order to simplify the exposition, we shall use (2.16) and introduce the following notation:

$$\{t_i\} = \{c_i\} \cup \{\hat{c}_i\}, \quad \{\omega_i\} = \{\beta_i\} \cup \{\hat{\beta}_i\},$$
$$y_i = \sigma(t_0 + t_i h), \quad f_i = f(\sigma(t_0 + t_i h)), \qquad i = 1, \dots, k.$$

The discrete problem defining the HBVM(k,s) then becomes,

$$y_i = y_0 + h \sum_{j=1}^{s} \int_0^{t_i} P_j(x)\mathrm{d}x \sum_{\ell=1}^{k} \omega_\ell P_j(t_\ell) f_\ell, \qquad i = 1, \dots, k. \tag{2.18}$$

By introducing the vectors

$$\mathbf{y} = (y_1^T, \dots, y_k^T)^T, \qquad e = (1, \dots, 1)^T \in \mathbb{R}^k,$$

and the matrices

$$\Omega = \mathrm{diag}(\omega_1, \dots, \omega_k), \qquad \mathscr{I}_s,\ \mathscr{P}_s \in \mathbb{R}^{k\times s}, \tag{2.19}$$

whose (i,j)th entry are given by

$$(\mathscr{I}_s)_{ij} = \int_0^{t_i} P_j(x)\mathrm{d}x, \qquad (\mathscr{P}_s)_{ij} = P_j(t_i), \tag{2.20}$$

we can cast the set of equations (2.18) in vector form as

$$\mathbf{y} = e \otimes y_0 + h(\mathscr{I}_s \mathscr{P}_s^T \Omega) \otimes I_{2m}\, f(\mathbf{y}),$$

with an obvious meaning of $f(\mathbf{y})$. Consequently, the method can be seen as a Runge-Kutta method with the following Butcher tableau:

$$\begin{array}{c|c} t_1 & \\ \vdots & \mathscr{I}_s \mathscr{P}_s^T \Omega \\ t_k & \\ \hline & \omega_1 \ \dots \ \omega_k \end{array} \tag{2.21}$$

Remark 5 *We observe that, because of the use of an orthonormal basis, the role of the abscissae $\{c_i\}$ and of the silent abscissae $\{\hat{c}_i\}$ is interchangeable, within the set $\{t_i\}$. This is due to the fact that all the matrices $\mathscr{I}_s$, $\mathscr{P}_s$, and Ω depend on all the abscissae $\{t_i\}$, and not on a subset of them, and they are invariant with respect to the choice of the fundamental abscissae $\{c_i\}$.*

Hereafter, we shall consider a Gauss distribution of the abscissae $\{t_1, \dots, t_k\}$, so that the resulting HBVM(k,s) method [6]:

– has order $2s$ for all $k \geq s$;
– is symmetric and perfectly A-stable (i.e., its stability region coincides with the left-half complex plane, $\mathbb{C}^-$ [14]);
– reduces to the Gauss-Legendre method of order $2s$, when $k = s$;
– exactly preserves polynomial Hamiltonian functions of degree ν, provided that

$$k \geq \frac{\nu s}{2}.$$

3 The Isospectral Property

We are now going to prove a further additional result, related to the matrix appearing in the Butcher tableau (2.21), corresponding to HBVM(k,s), i.e., the matrix

$$A = \mathscr{I}_s \mathscr{P}_s^T \Omega \in \mathbb{R}^{k\times k}, \qquad k \geq s, \tag{3.1}$$

whose rank is s. Consequently it has a $(k-s)$-fold zero eigenvalue. In this section, we are going to discuss the location of the remaining s eigenvalues of that matrix.

Before that, we state the following preliminary result, whose proof can be found in [17, page 79].

Lemma 1 *The eigenvalues of the matrix*

$$X_s = \begin{pmatrix} \frac{1}{2} & -\xi_1 & & \\ \xi_1 & 0 & \ddots & \\ & \ddots & \ddots & -\xi_{s-1} \\ & & \xi_{s-1} & 0 \end{pmatrix}, \tag{3.2}$$

with

$$\xi_j = \frac{1}{2\sqrt{(2j+1)(2j-1)}}, \qquad j \geq 1, \tag{3.3}$$

coincide with those of the matrix in the Butcher tableau of the Gauss-Legendre method of order $2s$.

We also need the following preliminary result, whose proof derives from the properties of shifted-Legendre polynomials (see, e.g., [1] or the Appendix in [5]).

Lemma 2 *With reference to the matrices in (2.19)–(2.20), one has*

$$\mathscr{I}_s = \mathscr{P}_{s+1} \hat{X}_s,$$

where

$$\hat{X}_s = \left(\begin{array}{cccc} \frac{1}{2} & -\xi_1 & & \\ \xi_1 & 0 & \ddots & \\ & \ddots & \ddots & -\xi_{s-1} \\ & & \xi_{s-1} & 0 \\ \hline & & & \xi_s \end{array}\right),$$

with the ξ_j *defined by (3.3).*

The following result then holds true.

Theorem 1 (Isospectral Property of HBVMs) *For all $k \geq s$ and for any choice of the abscissae $\{t_i\}$ such that the quadrature defined by the weights $\{\omega_i\}$ is exact for polynomials of degree $2s-1$, the nonzero eigenvalues of the matrix A in (3.1) coincide with those of the matrix of the Gauss-Legendre method of order $2s$.*

Proof For $k = s$, the abscissae $\{t_i\}$ have to be the s Gauss-Legendre nodes, so that HBVM(s,s) reduces to the Gauss Legendre method of order $2s$, as outlined at the end of Section 2.

When $k > s$, from the orthonormality of the basis, see (2.7), and considering that the quadrature with weights $\{\omega_i\}$ is exact for polynomials of degree (at least) $2s-1$, one easily obtains that (see (2.19)–(2.20))

$$\mathscr{P}_s^T \Omega \mathscr{P}_{s+1} = (I_s \ \mathbf{0}),$$

since, for all $i = 1,\dots,s,$ and $j = 1,\dots,s+1$:

$$\left(\mathscr{P}_s^T \Omega \mathscr{P}_{s+1}\right)_{ij} = \sum_{\ell=1}^{k} \omega_\ell P_i(t_\ell) P_j(t_\ell) = \int_0^1 P_i(t) P_j(t) \mathrm{d}t = \delta_{ij}.$$

By taking into account the result of Lemma 2, one then obtains:

$$\begin{aligned} A\mathscr{P}_{s+1} = \mathscr{I}_s \mathscr{P}_s^T \Omega \mathscr{P}_{s+1} = \mathscr{I}_s (I_s \ \mathbf{0}) = \mathscr{P}_{s+1} \hat{X}_s (I_s \ \mathbf{0}) = \mathscr{P}_{s+1} \left(\hat{X}_s \ \mathbf{0}\right) \\ \equiv \mathscr{P}_{s+1} \left(\begin{array}{cccc|c} \frac{1}{2} & -\xi_1 & & & 0 \\ \xi_1 & 0 & \ddots & & \vdots \\ & \ddots & \ddots & -\xi_{s-1} & \vdots \\ & & \xi_{s-1} & 0 & 0 \\ \hline & & & \xi_s & 0 \end{array}\right) \end{aligned}$$

with the $\{\xi_j\}$ defined according to (3.3). Consequently, one obtains that the columns of $\mathscr{P}_{s+1}$ constitute a basis of an invariant (right) subspace of matrix A, so that the eigenvalues of $(\hat{X}_s \ \mathbf{0})$ are eigenvalues of A. In more detail, the eigenvalues of $(\hat{X}_s \ \mathbf{0})$ are those of X_s (see (3.2)) and the zero eigenvalue. Then, also in this case, the nonzero eigenvalues of A coincide with those of X_s, i.e., with the eigenvalues of the matrix defining the Gauss-Legendre method of order $2s$. □

4 Solving the discrete problem

We shall now consider some computational aspects concerning HBVM(k,s). In more details, we now show how its cost depends essentially on s, rather than on k, in the sense that the nonlinear system to be solved, for obtaining the discrete solution, has (block) dimension s. This has been already shown in [5], but here we derive the same result in a slightly more compact way, which will allow us to easily introduce *blended HBVMs* in the next section.

In order to simplify the notation, we shall fix the fundamental stages at $t_1,\dots,t_s$, since we have already seen that, due to the use of an orthonormal basis , they could be in principle chosen arbitrarily, among the abscissae $\{t_i\}$. With this premise, we have, from (2.15),

$$y_i = y_0 + h\sum_{j=1}^{s} a_{ij}\sum_{\ell=1}^{k}\omega_\ell P_j(t_\ell)\,f_\ell, \qquad i=1,\dots,s. \tag{4.1}$$

This equation is now coupled with that defining the silent stages, i.e., from (2.6) and (2.10),

$$y_i = y_0 + \sum_{j=1}^{s}\gamma_j\int_0^{t_i} P_j(t)\mathrm{d}t, \qquad i=s+1,\dots,k. \tag{4.2}$$

Let us now partition the matrices $\mathscr{I}_s,\mathscr{P}_s\in\mathbb{R}^{k\times s}$ in (2.19)–(2.20) into $\mathscr{I}_{s1},\mathscr{P}_{s1}\in\mathbb{R}^{s\times s}$ and $\mathscr{I}_{s2},\mathscr{P}_{s2}\in\mathbb{R}^{k-s\times s}$, containing the entries defined by the fundamental abscissae and the silent abscissae, respectively. Similarly, we partition the vector $\mathbf{y}$ into $\mathbf{y}_1$, containing the fundamental stages, and $\mathbf{y}_2$ containing the silent stages and, accordingly, let $\boldsymbol{\Omega}_1\in\mathbb{R}^{s\times s}$ and $\boldsymbol{\Omega}_2\in\mathbb{R}^{k-s\times k-s}$ be the diagonal matrices containing the corresponding entries in matrix $\boldsymbol{\Omega}$. Finally, let us define the vectors $\boldsymbol{\gamma}=(\gamma_1^T,\dots,\gamma_s^T)^T$, $e=(1,\dots,1)^T\in\mathbb{R}^s$, and $u=(1,\dots,1)^T\in\mathbb{R}^{k-s}$.
Consequently, we can rewrite (4.1) and (4.2), as

$$\mathbf{y}_1 = e\otimes y_0 + h\mathscr{I}_{s1}\left(\mathscr{P}_{s1}^T\ \mathscr{P}_{s2}^T\right)\begin{pmatrix}\boldsymbol{\Omega}_1 & \\ & \boldsymbol{\Omega}_2\end{pmatrix}\otimes I_{2m}\begin{pmatrix} f(\mathbf{y}_1)\\ f(\mathbf{y}_2)\end{pmatrix}, \tag{4.3}$$

$$\mathbf{y}_2 = u\otimes y_0 + h\mathscr{I}_{s2}\otimes I_{2m}\boldsymbol{\gamma}, \tag{4.4}$$

respectively. The vector $\boldsymbol{\gamma}$ can be easily retrieved from the identity (2.14), which in vector form reads

$$\mathbf{y}_1 = e\otimes y_0 + h\mathscr{I}_{s1}\otimes I_{2m}\boldsymbol{\gamma},$$

thus giving

$$\begin{aligned}\mathbf{y}_2 &= \left(u - \mathscr{I}_{s2}\mathscr{I}_{s1}^{-1}e\right)\otimes y_0 + \mathscr{I}_{s2}\mathscr{I}_{s1}^{-1}\otimes I_{2m}\mathbf{y}_1\\ &\equiv \hat{u}\otimes y_0 + A_1\otimes I_{2m}\mathbf{y}_1,\end{aligned} \tag{4.5}$$

in place of (4.4), where, evidently, $A_1\in\mathbb{R}^{k-s\times s}$. By setting

$$B_1 = \mathscr{I}_{s1}\mathscr{P}_{s1}^T\boldsymbol{\Omega}_1\in\mathbb{R}^{s\times s}, \qquad B_2 = \mathscr{I}_{s1}\mathscr{P}_{s2}^T\boldsymbol{\Omega}_2\in\mathbb{R}^{s\times k-s}, \tag{4.6}$$

substitution of (4.5) into (4.3) then provides, at last, the system of (block) size s to be actually solved:

$$\begin{aligned}F(\mathbf{y}_1)\equiv \mathbf{y}_1 - e\otimes y_0 - h\,[&B_1\otimes I_{2m}f(\mathbf{y}_1) +\\ &B_2\otimes I_{2m}f\left(\hat{u}\otimes y_0 + A_1\otimes I_{2m}\mathbf{y}_1\right)] = \mathbf{0}.\end{aligned} \tag{4.7}$$

By using the simplified Newton method for solving (4.7), and setting

$$C = B_1 + B_2A_1\in\mathbb{R}^{s\times s}, \tag{4.8}$$

one obtains the iteration:

$$\begin{aligned}(I_s \otimes I_{2m} - hC \otimes J_0)\,\delta^{(n)} &= -F(\mathbf{y}_1^{(n)}) \equiv \boldsymbol{\psi}_1^{(n)}, \\ \mathbf{y}_1^{(n+1)} &= \mathbf{y}_1^{(n)} + \delta^{(n)}, \qquad n = 0,1,\ldots,\end{aligned} \tag{4.9}$$

where J_0 is the Jacobian of $f(y)$ evaluated at y_0. Because of the result of Theorem 1, the following property of matrix C holds true.

Theorem 2 *The eigenvalues of matrix C in (4.8) coincide with those of matrix (3.2), i.e., with the eigenvalues of the matrix of the Butcher array of the Gauss-Legendre method of order* 2*s.*

Proof Assuming, as usual for simplicity, that the fundamental stages are the first s ones, one has that the discrete problem

$$\mathbf{y} = \begin{pmatrix} e \\ u \end{pmatrix} \otimes y_0 + hA \otimes I_{2m} f(\mathbf{y}),$$

which defines the Runge-Kutta formulation of the method, is equivalent, by virtue of (4.3), (4.5), (4.6), to

$$\begin{pmatrix} I_s & O_{s\times r} \\ -A_1 & I_r \end{pmatrix} \otimes I_{2m} \begin{pmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \end{pmatrix} = \begin{pmatrix} e \\ \hat{u} \end{pmatrix} \otimes y_0 + h \begin{pmatrix} B_1 & B_2 \\ O_{r\times s} & O_{r\times r} \end{pmatrix} \otimes I_{2m} \begin{pmatrix} f(\mathbf{y}_1) \\ f(\mathbf{y}_2) \end{pmatrix},$$

where, as usual, $r = k - s$.[2] Consequently, the eigenvalues of the matrix A defined in (3.1) coincide with those of the matrix pencil

$$\left(\begin{pmatrix} I_s & O_{s\times r} \\ -A_1 & I_r \end{pmatrix}, \begin{pmatrix} B_1 & B_2 \\ O_{r\times s} & O_{r\times r} \end{pmatrix} \right),$$

that is

$$\mu \in \sigma(A) \;\Leftrightarrow\; \mu \begin{pmatrix} I_s & O_{s\times r} \\ -A_1 & I_r \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \end{pmatrix} = \begin{pmatrix} B_1 & B_2 \\ O_{r\times s} & O_{r\times r} \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \end{pmatrix},$$

for some nonzero vector $(\mathbf{u}^T, \mathbf{v}^T)^T$. By setting $\mathbf{u} = \mathbf{0}$, one obtains the r zero eigenvalues of the pencil. For the remaining s (nonzero) ones, it must be $\mathbf{v} = A_1\mathbf{u}$, so that:

$$\mu\mathbf{u} = (B_1\mathbf{u} + B_2\mathbf{v}) = (B_1\mathbf{u} + B_2A_1\mathbf{u}) = C\mathbf{u} \;\Leftrightarrow\; \mu \in \sigma(C). \;\square$$

Remark 6 *From the result of Theorem 2, it follows that the spectrum of C doesn't depend on the choice of the s fundamental abscissae, within the nodes* $\{t_i\}$*. On the contrary, its condition number does: the latter appears to be minimized when the fundamental abscissae are symmetrically distributed, and approximately evenly spaced, in the interval* $[0,1]$*. As a practical* "rule of thumb"*, the following algorithm appears to be almost optimal:*[3]

[2] As observed in [19,22], such formulation fits the framework of block BVMs.

[3] We plan to investigate this aspect further, in a forthcoming paper.

1. *let the k abscissae $\{t_i\}$ be chosen according to a Gauss-Legendre distribution of k nodes;*
2. *then, let us consider s equidistributed nodes in $(0,1)$, say $\{\hat{t}_1,\ldots,\hat{t}_s\}$;*
3. *select, as the fundamental abscissae, those nodes, among the $\{t_i\}$, which are the closest ones to the $\{\hat{t}_j\}$;*
4. *define matrix C in (4.8) accordingly.*

Clearly, for the above algorithm to provide a unique solution (resulting in a symmetric choice of the fundamental abscissae), the difference $k-s$ has to be even which, however, can be easily accomplished.

In order to give evidence of the effectiveness of the above algorithm, in Figure 4.1 we plot the condition number of matrix $C = C(k,s)$, for $s = 2,\ldots,5$, and $k \geq s$. As one can see, the condition number of $C(k,s)$ turns out to be nicely bounded, for increasing values of k, which makes the implementation (that we are going to analyze in the next section) effective also when finite precision arithmetic is used. For comparison, in Figure 4.2 there is the same plot, obtained by fixing the fundamental abscissae as the first s ones.

5 Blended HBVMs

The solution of problem (4.9) is now cast into the framework of *blended implicit methods* [2,7,8,9,10,13,15,23] as below described. First of all, we observe that, since C is nonsingular, we can recast problem (4.9) in the *equivalent form*

$$\gamma\left(C^{-1}\otimes I_{2m} - hI_s\otimes J_0\right)\delta^{(n)} = -\gamma C^{-1}\otimes I_{2m}F(\mathbf{y}_1^{(n)}) \equiv \boldsymbol{\psi}_2^{(n)}, \tag{5.1}$$

where $\gamma > 0$ is a free parameter to be chosen later. Let us now introduce the *weight (matrix) function*

$$\theta = I_s\otimes\Phi^{-1}, \qquad \Phi = I_{2m} - h\gamma J_0 \in \mathbb{R}^{2m\times 2m}, \tag{5.2}$$

and the *blended formulation* of the system to be solved,

$$\begin{aligned} M\delta^{(n)} &\equiv \left[\theta\left(I_s\otimes I_{2m} - hC\otimes J_0\right) + \right.\\ &\qquad \left.(I-\theta)\gamma\left(C^{-1}\otimes I_{2m} - hI_s\otimes J_0\right)\right]\delta^{(n)}\\ &= \theta\boldsymbol{\psi}_1^{(n)} + (I-\theta)\boldsymbol{\psi}_2^{(n)} \equiv \boldsymbol{\psi}^{(n)}. \end{aligned} \tag{5.3}$$

The latter system has still the same solution as the previous ones, since it is obtained as the *blending*, with weights θ and $(I-\theta)$, of the two equivalent forms (4.9) and (5.1). For iteratively solving (5.3), we use the corresponding *blended iteration*, formally given by [2,7,8,9,10,13,15,23]:

$$\delta^{(n,\ell+1)} = \delta^{(n,\ell)} - \theta\left(M\delta^{(n,\ell)} - \boldsymbol{\psi}^{(n)}\right), \qquad \ell = 0,1,\ldots. \tag{5.4}$$

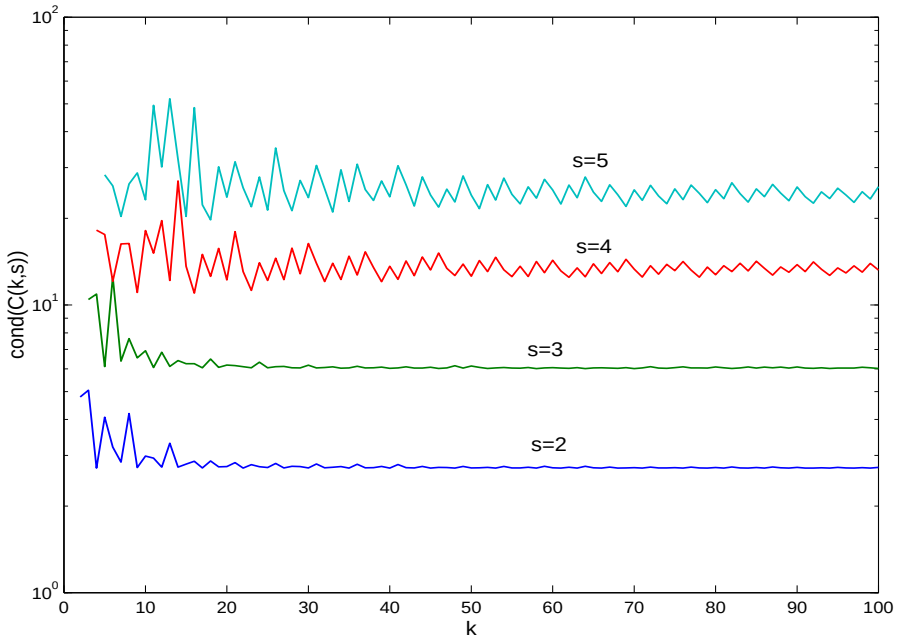

Fig. 4.1 Condition number of the matrix $C = C(k,s)$, for $s = 2,3,4,5$ and $k = s, s+1, \ldots, 100$, with the fundamental abscissae chosen according to the algorithm sketched in Remark 6.

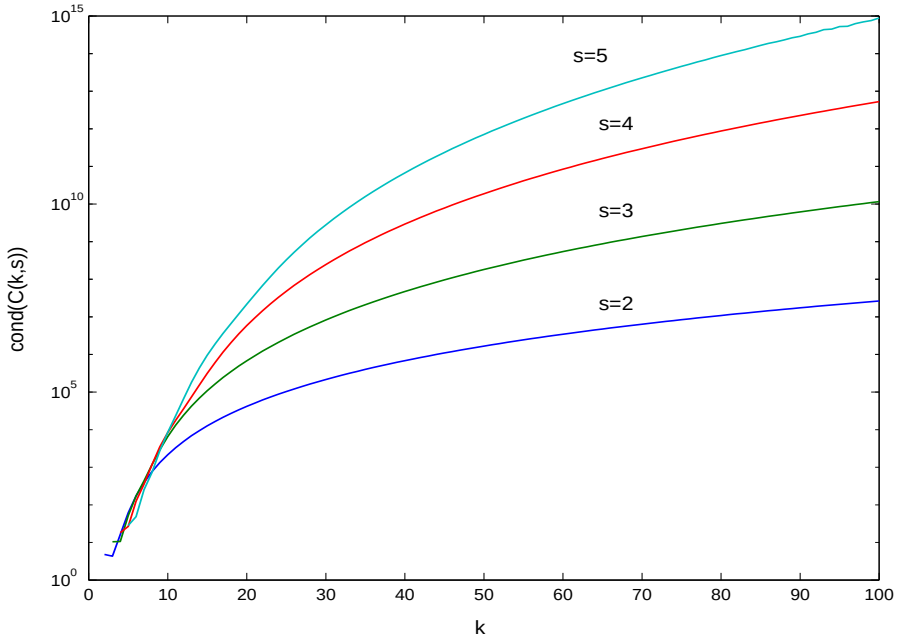

Fig. 4.2 Condition number of the matrix $C = C(k,s)$, for $s = 2,3,4,5$ and $k = s, s+1, \ldots, 100$, with the fundamental abscissae chosen as the first s ones.

Remark 7 *A nonlinear variant of the iteration (5.4) can be obtained, by setting*

$$\mathbf{y}^{(n,\ell+1)} = \mathbf{y}^{(n,\ell)} + \delta^{(n,\ell)}, \qquad \boldsymbol{\psi}_1^{(n,\ell)} = -F\left(\mathbf{y}_1^{(n,\ell)}\right),$$

$\boldsymbol{\psi}_2^{(n,\ell)}$ *and* $\boldsymbol{\psi}^{(n,\ell)}$ *similarly defined, as:*

$$\delta^{(n,\ell+1)} = \delta^{(n,\ell)} - \theta\left(M\delta^{(n,\ell)} - \boldsymbol{\psi}^{(n,\ell)}\right), \qquad \ell = 0,1,\ldots. \tag{5.5}$$

Remark 8 *We emphasize that, for actually performing the iteration (5.2)–(5.4), as well as (5.5), one has to factor only the matrix Φ in (5.2), which has the same size as that of the continuous problem, due to the (block) diagonal structure of θ.*

We end this section by observing that the above iteration (5.4) depends on a free parameter γ. It will be chosen in order to optimize the convergence properties of the iteration, according to a linear analysis of convergence, which is sketched in the next section.

6 Linear analysis of convergence

The linear analysis of convergence for the iterations (5.4) is carried out by considering the usual scalar test equation (see, e.g., [11] and the references therein),

$$y' = \lambda y, \qquad \Re(\lambda) < 0.$$

By setting, as usual $q = h\lambda$, the two equivalent formulations (4.9) and (5.1) become, respectively (omitting, for sake of brevity, the upper index n),

$$(I_s - qC)\delta = \boldsymbol{\psi}_1, \qquad \gamma(C^{-1} - qI_s)\delta = \boldsymbol{\psi}_2.$$

Moreover,

$$\theta \equiv \theta(q) = (1-\gamma q)^{-1} I_s, \tag{6.1}$$

and the blended iteration (5.4) becomes

$$\delta^{(\ell+1)} = (I_s - \theta(q)M(q))\delta^{(\ell)} + \theta(q)\boldsymbol{\psi}(q), \tag{6.2}$$

with

$$\begin{aligned} M(q) &= \theta(q)\,(I_s - qC) + (I_s - \theta(q))\gamma\left(C^{-1} - qI_s\right), \\ \boldsymbol{\psi}(q) &= \theta(q)\boldsymbol{\psi}_1 + (I_s - \theta(q))\boldsymbol{\psi}_2. \end{aligned} \tag{6.3}$$

Consequently, the iteration will be convergent if and only if the spectral radius, say $\rho(q)$, of the iteration matrix,

$$Z(q) = I_s - \theta(q)M(q), \tag{6.4}$$

is less than 1. The set

$$\Gamma = \{q \in \mathbb{C} : \rho(q) < 1\}$$

is the *region of convergence of the iteration*. The iteration is said to be (see [11] for details):

– A-convergent, if $\mathbb{C}^- \subseteq \Gamma$;
– L-convergent, if it is A-convergent and, moreover, $\rho(q) \to 0$, as $q \to \infty$.

For the iteration (6.2) one verifies that (see (6.1), (6.3), and (6.4))

$$Z(q) = \frac{q}{(1-\gamma q)^2} C^{-1} (C - \gamma I_s)^2, \tag{6.5}$$

which is the null matrix at $q = 0$ and at ∞. Consequently, the iteration will be A-convergent (and, therefore, L-convergent), provided that *maximum amplification factor*,

$$\rho^* \equiv \max_{\Re(q)=0} \rho(q) \ \leq 1.$$

From (6.5) one has that [4]

$$\mu \in \sigma(C) \ \Leftrightarrow \ \frac{q(\mu-\gamma)^2}{\mu(1-\gamma q)^2} \in \sigma(Z(q)).$$

By taking into account that

$$\max_{\Re(q)=0} \frac{|q|}{|(1-\gamma q)^2|} = \frac{1}{2\gamma},$$

one then obtains that

$$\rho^* = \max_{\mu\in\sigma(C)} \frac{|\mu-\gamma|^2}{2\gamma|\mu|}.$$

For the Gauss-Legendre methods (and, then, for any matrix C having the same spectrum), it can be shown that [7, 13] the choice

$$\gamma = |\mu_{\min}| \equiv \min_{\mu\in\sigma(C)} |\mu|, \tag{6.6}$$

minimizes ρ^*, which turns out to be given by

$$\rho^* = 1 - \cos\varphi_{\min} \ < 1, \qquad \varphi_{\min} = \mathrm{Arg}(\mu_{\min}). \tag{6.7}$$

In Table 6.1, we list the optimal value of the parameter γ, along with the corresponding maximum amplification factor ρ^*, for various values of s, which confirm that the iteration (6.2) is L-convergent.

Remark 9 *We then conclude that the* blended iteration *(5.4) turns out to be L-convergent for HBVM(k,s) methods, for all $s \geq 1$ and $k \geq s$.*

[4] Hereafter, $\sigma(C)$ will denote the spectrum of matrix C.

Table 6.1 Optimal values (6.6), and corresponding maximum amplification factors (6.7), for various values of s.

s	γ	ρ^*
2	0.2887	0.1340
3	0.1967	0.2765
4	0.1475	0.3793
5	0.1173	0.4544

7	0.0827	0.5561
8	0.0718	0.5921
9	0.0635	0.6218
10	0.0568	0.6467

7 Conclusions

In this paper, computational aspects related to the efficient implementation of *HBVM methods with k steps and degree s ($k \geq s$) (in short, HBVM(k,s))*, have been recast in the framework of *blended implicit methods*. In more details, we have seen that the discrete problem generated by HBVM(k,s) amounts to a nonlinear system of (block) dimension s. Its efficient solution can be obtained by considering the *blended formulation* of the discrete problem, for which an efficient *diagonal splitting* can be easily defined. Consequently, to implement the nonlinear iteration, only *one* matrix having the same size as that of the continuous problem has to be factored. The free parameter, on which the *blended iteration* depends on, can be easily chosen, because of the *isospectral property* of HBVM(k,s), resulting in an *L-convergent iteration*. Last, but not least, also the conditioning of the discrete problem depends only on s, and it appears to tend to a (nicely) bounded limit, as k grows. We plan, in the future, to implement HBVMs in blended formulation (in short, *blended HBVMs*), in a computational code for numerically solving Hamiltonian problems.
